Semester 1 Year 11 Physics Exam Revision Solutions

Topics covered by exam:

- Scientific Method
- Thermal Physics
- Electrical Physics
- Introduction to Nuclear Physics

Resources:

- Attached worksheets
- Questions in topic booklets
- STAWA exercises
- Pearson chapter review questions
- WACE Study guide

Revision timeline

Date	Milestone
Thursday week 3	Electricity revision completed
Friday week 3	Electricity Topic Test
Friday week 4	Thermal revision completed
Friday week 5	Nuclear and Scientific Method revision completed
Week 6	Exams commence

Electricity

1. A portable stereo runs off four 1.50 V cells connected in series. The total resistance of the stereo when used to play music is 18.0 Ω
    a. How much current does the stereo draw from the cells? 0.333 A
    b. If it is used for half an hour how much charge flows through the electric circuit of the stereo? 600 C

2. A particular sensor system is used to sample data at regular intervals. The data are then transmitted along metal cables before storage by a computer for future analysis. The average current carried by the sensor system is 35 mA and the effective sensor resistance is 22 kΩ.
    a. Calculate the heat energy dissipated in the system in a 24 hour period. 2 330 000 J
    b. In an attempt to increase the versatility of the sensor system, the diameter of the cables is reduced. Suggest a disadvantage of reducing the diameter of the cables. Increase resistance, decreasing current.

3. A toaster is marked 240 V, 1250 W.
    a. What current does it draw from the mains? 5.21 A
    b. If the owner of the toaster uses it for 2 hours per week, how much would it cost to operate per week if electricity costs 15 cents per every 3.6 MJ? $0.375

4. A personal hand held fan had four 1.5 V cells connected in series which drive a small electric motor. The dan had two speed settings as controlled by adjusting the switches in the circuit.

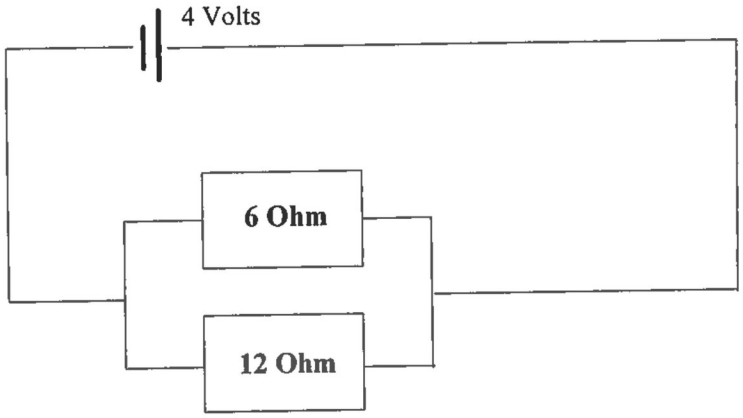
    Two resistors whose value is indicated are included in the circuit.

    a. When all the switches are closed what is the total resistance of the circuit? The motor has a resistance of 3 Ω. 4 Ω

b. With respect to the switches S1 and S2 which position should they be for maximum motor speed? Give your reason. S1: closed, otherwise no current will flow at all. S2: closed, will decrease total resistance, increasing total current through the motor.

5.

a. Determine the current flowing through the 6 Ohm resistor in the diagram below. 0.667 A



b. How many electrons pass through the 6 Ohm resistor each second? 4.17×10^{18}

6. A group of physics students were asked to find the value of the resistance of a device in a circuit. The table below shows the generated results.

Potential difference (V)	1.2	1.8	2.2	3.0	3.4	3.7	4.2	4.8
Current (mA)	140	210	256	350	410	430	490	560

a. Using correct symbols draw a circuit diagram to show a simple experimental setup the students were likely to have used to have attained the data above.
b. Graph the data and comment on what information the shape of the graph provides. Straight line, therefore constant resistance, therefore it is an ohmic device.
c. Show working to calculate the resistance of the device as determined in the experiment. 8.54 Ω
d. Would it be safe to assume that the resistance of the circuit would remain constant above 5.0 V? No, many devices are ohmic at low voltage but not at higher voltages. Also it would be extrapolation which is generally risky.
e. If the battery stores 100.0 C of charge, how long will the circuit operate at 4.0 V? 214 s

7. An electric coffee maker has a resistance of 75.0 Ω and operates on a 240 V supply. 85% of the electrical energy is converted into heating 0.50 kg of water which is initially at 23°C.
a. Calculate the heat energy required to just bring the water to its boiling point. 161 000 J
b. Calculate the quantity of electrical energy required to boil the water. 189 000 J
c. Calculate the time taken to boil the water. 247 s

8. Resistivity is a property of a material that determines the electrical resistance of that material. Other variables that determine the resistance are length and cross-sectional area. They are related by the formula:

$$R = \frac{\rho l}{A}$$

A group of Year 11 students were given the task of finding the resistivity of graphite in a "lead" pencil. The diameter of the graphite in the pencil was 2.0 mm.

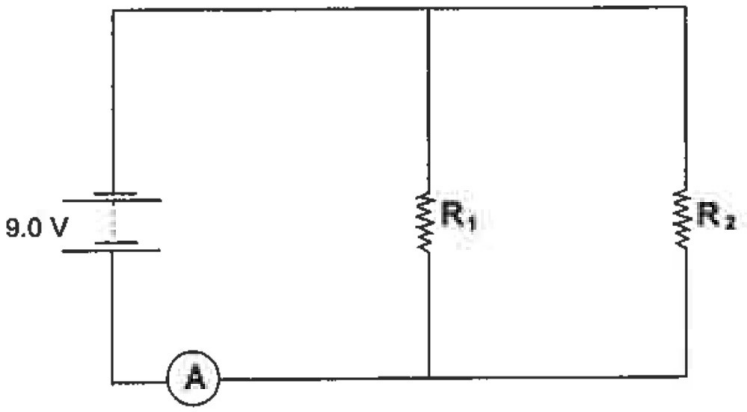
The voltage was determined by connecting a voltmeter to the graphite via crocodile clips. Their results are summarized below:

Length of "lead" (x 10^{-2} m)	Current (A)	Voltage (V)	Resistance (Ω)
10.0	0.29	1.74	6
8.0	0.35	1.73	4.94
6.0	0.41	1.67	4.07
4.0	0.53	1.49	2.81
2.0	0.69	1.27	1.84

a. Use the results table and complete the column headed "Resistance".
b. Plot a graph of Resistance (y axis) against Length (x axis) and draw a line of best fit.
c. Use the gradient of the "line of best fit" and the cross-sectional area of the "lead" to determine the resistivity of the graphite. 1.64 x10^{-4} Ω m
d. Why does the graph not pass through the origin (0,0)? Could be cause by internal resistance of the power supply, leading to an overall higher resistance for the circuit than if it were just resistance from the "lead".

9. One tiny polystyrene ball carries a positive charge while another carries a negative charge. The two balls are hung vertically on 1cm strings from a rod. They are 5 cm apart.
   a. Sketch how the balls would sit when undisturbed. The balls would not sit vertically, they would be pulled towards each other.
   b. If the balls were brought together and touched what would happen to the charges? Why? If they were small enough they may exchange electrons and neutralise each others' charges, however as insulators they may not and may just stick to each other. This is because the electrons can not freely move around in insulators.

10. A student sets up a circuit represented by the circuit diagram below.



The reading on the ammeter is 1.35 A. The resistance of R_2 is 10.0 Ω but the resistance of R_1 is unknown.

a. Calculate the current flowing through R_2. 0.9 A
b. Calculate the current flowing through R_1. 0.45 A
c. Calculate the resistance of R_1. 20 Ω
d. Calculate the effective resistance of the circuit. 6.67 Ω

Thermal Physics

1. A plastic insulated container contains 300 g of water at 20 °C. If 50 g ice at 0 °C is added to the water, calculate the final temperature of the water. (Ignore any heat transfer between the mixture and the container.)

6.17 °C

2. Explain why steaming cooks faster than boiling. Steam has more energy than water at the same temperature because it contains the latent heat of vaporisation in addition to the energy held due to its temperature. In contact with food the steam has more energy to transfer to the food.

3. On a warm sunny day, the sun's radiation melts very little snow on the slopes of an alpine ski resort. Why? The snow is a reflective white colour reflecting most of the solar radiation. It only absorbs a small amount of energy leading to only a small amount of melting.

4. 585 kg of pyrex glass (specific heat 837 J kg^{-1} K^{-1}) loses 8.65 x 10^6 J of heat. If the temperature of the glass is 95.8 °C before cooling, what is its final temperature? 78.1°C

5. What mass of water can be raised in temperature from 15°C to its boiling point when 2.93x10^6 J of heat is supplied? 8.25 kg

6. A glass beaker of mass 215 g contains 145 g of water at 18.5 °C. If the specific heat of glass is 840 J kg^{-1} K^{-1}, how much heat energy would need to be supplied to raise the temperature of the glass and water to 98.5°C? 62900 J

7. Calculate the specific heat of a piece of steel if 5.53x10^7 J of heat is required to heat a 286 kg mass of the steel from 22 °C to 452 °C. 450 J kg^{-1} K^{-1}

8. Why does a foot in a wet sock usually feel colder than a foot in a dry sock even if both socks have the same temperature? A foot in a dry sock is insulated by trapped pockets of air in the sock while a foot in a wet sock can easily lose heat to the water by conduction. The loss of heat is responsible for the feeling of being cold.

9. In hot weather, it is not uncommon for pet dogs to stretch out on a tiled floor. Why do they choose a tiled floor rather than other surfaces? The tile floor is a better conductor than a carpet floor, the dog will more quickly lose energy to the tile floor allowing it to cool down faster.

10. How much heat energy must a fridge remove from an aluminium pot of mass 865 g to cool it from a temperature of 120 °C to 55 °C. (c_{Al}= 900 J kg^{-1} K^{-1}) 50600 J

11. How much heat does 28.6 kg of ice at 0 °C absorb while it melts completely? 9550000 J

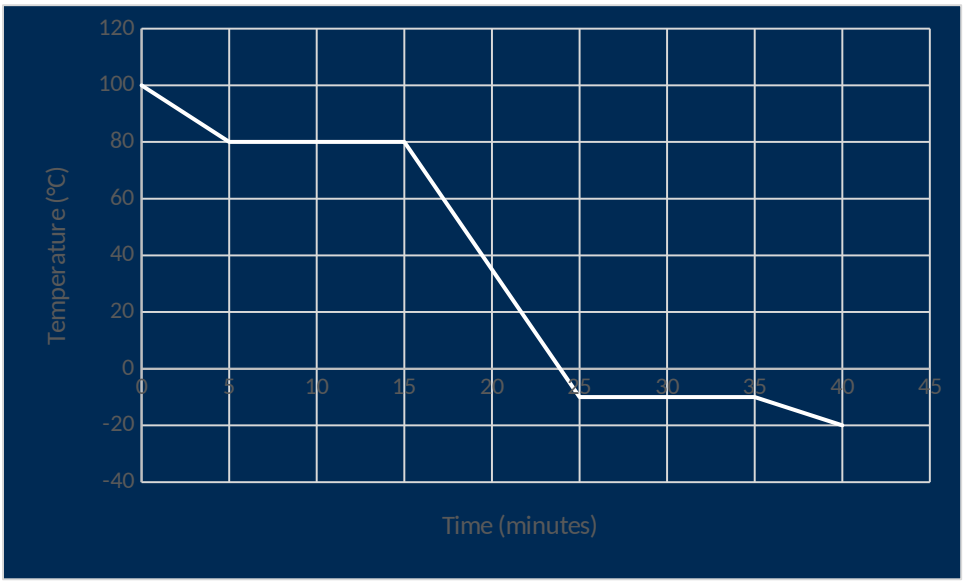
12. How much heat energy does 423 g of steam at 100 °C release when it condenses to water at the same temperature? 956000 J

13. A student freezes a drink bottle containing 1.15 kg of tap water at 21.5 °C. How much heat energy must the freezer remove from the drink to turn it into ice at a temperature of -5 °C. 500000 J

14. Using kinetic theory, explain why:
    a. The pressure increases when more air is put into a car tyre. The particles in the tyre are closer together and more tightly packed so the rate of collisions with the walls of the tyre will increase.
    b. It is dangerous to put an aerosol can on a fire. The particles inside will gain a lot of kinetic energy, increasing their speed, and thus how often and forcefully they collide with the walls of the can. This will increase the internal pressure until it exceeds what the can is capable of resisting and so it will burst violently.
    c. A lady's perfume can be detected at some distance from her, even when there are no draughts. Gas particles move randomly in straight lines. A wind would be needed to carry all the perfume particles as a group but individual particles can quickly spread out over large areas. For strong perfumes it does not take a large concentration to be able to smell them.

15. Why do solids not increase in temperature while they are melting even though heat energy continues to be supplied? During a phase change, all added energy is becoming potential energy in stretching and then breaking the bonds.

16. Construct a cooling curve illustrating a gas cooling until it liquifies at 80 °C, the resulting liquid cooling until it solidifies at -10 °C and the solid cooling further to -20 °C.



17. What is wind chill?
    As wind blows across your body there are collisions between air particles and the particles of your body.

18. Water is a good absorber of radiated heat energy. Why, then, does it not get hot very quickly?

Water has a very high specific heat capacity so it requires large quantities of energy to change in temperature significantly. Another substance that is less good at absorbing radiation may still heat more quickly if it has a much lower specific heat capacity.

19. Explain why
    a. Telephone wires are left slack when hung between poles.
       In cold weather the wires will contract, shortening, there needs to be enough length to still span the distance when cold
    b. Concrete roads have bitumen-filled gaps across them.
       The concrete will expand when weather is hot, the gaps allow room for it to expand into without damaging itself.
    c. Steel can be used to reinforce concrete.
       Referring to the table below it can be seen that concrete and steel expand at the same rate so they can be mixed without one breaking the other due to expansion or contraction.

Expansion of 1 metre bar, heated to 100 °C	
Pyrex	0.3 mm
Platinum alloy	0.9 mm
Glass	0.9 mm
Concrete	1.0 mm
Steel	1.0 mmm

20. Explain why:
    a. An aluminium window frame feels cold when you touch it, but a wooden frame feels warmer.

Aluminium is a good conductor of heat and will be cooler than human body temperature. This means that energy will flow rapidly from your body to the aluminium. This is felt as a cold sensation. The wood will also be cooler than your temperature but is a poor conductor so energy will only very slowly flow from your body to the wood so it will fell much less cold.

    b. Aerated concrete is a better insulator than normal concrete.
       The trapped air bubbles in the aerated concrete contain gas which is a very poor conductor, much worse than the concrete itself. This is because the particles are much more spread out in the gas and are only weakly connected to each other. This leads to a reduction of the conductivity of the air-concrete mix overall.

21. Ibrahim feels a draught when the bonfire burns fiercely. Why?
    The bonfire causes the air around it to expand, becoming less dense and therefore rising. This leads to an updraft over the bonfire. The updraft causes low air pressure around the fire so air from around the outside is drawn inwards towards the fire creating a draught.

22. Explain why:
    a. If you tip methylated spirits on the back of your hand, the methylated spirit vanishes and your hand feels cold.
       Methylated spirits is volatile (evaporates very easily (low BP)) so it rapidly evaporates absorbing the latent heat of vaporization from your hand cooling it.
    b. On a humid day, you feel hot and uncomfortable.
       If there is more water already in the air your sweat takes much longer to evaporate. With less of your sweat evaporating you are not losing as much energy to the latent heat of vaporization so your sweat is not effectively cooling you so you feel too hot.

23. Explain how the breeze can cause a cooling effect on a person.
    air movement encourages evaporation, the breeze causes your sweat to evaporate more quickly, absorbing the latent heat of vaporization more quickly, cooling you.

OR

    As the air particles collide with your body they can exchange energy with the particles making up your body. Since the air is a lower temperature than your body, the net effect will be a transfer of energy from your body to the air. A breeze causes more collisions between your body and the air so the cooling effect is increased. You are losing heat by convection.

24. Draw a heating curve and give a detailed explanation of the curve as heat is applied.

As the solid is heated it gains kinetic energy causing the particles to vibrate faster, raising temperature. It also gains potential energy causing the particles to stretch further apart, causing the substance to expand.

As the substance melts it does not gain kinetic energy so the temperature does not change. It does gain potential energy causing the particles to stretch and then break their bonds as they change phase.

As the liquid is heated it gains kinetic energy causing the particles to vibrate faster, raising temperature. It also gains potential energy causing the particles to stretch further apart, causing the substance to expand.

As the substance boils it does not gain kinetic energy so the temperature does not change. It does gain potential energy causing the particles to stretch and then break their bonds as they change phase.

As the gas is heated it gains kinetic energy causing the particles to vibrate faster, raising temperature. It also gains potential energy causing the particles to stretch further apart, causing the substance to expand.

25. Why does the brass handle of the door feel colder than the wooden door itself when you touch them even though they are the same temperature?
    Brass is a good conductor of heat and will be cooler than human body temperature. This means that energy will flow rapidly from your body to the brass. This is felt as a cold sensation. The wood will also be cooler than your temperature but is a poor conductor so energy will only very slowly flow from your body to the wood so it will fell much less cold.

26. How much heat is required to melt 28.6 kg of ice at 0 °C?

9550000 J

27. How much heat energy is required to heat 1.15 kg of ice at 0 °C to water at 21.5 °C?
    487000 J
28. How many joules of energy are lost if 865 g of aluminium (c_{Al} = 880 J kg^{-1} K^{-1}) is cooled from 120 to 55 °C?
    49500 J
29. A glass beaker of mass 100 g contains 120 g of water 20 °C. If the specific heats of water and glass are 4200 J kg^{-1} K^{-1} and 840 J kg^{-1} K^{-1} respectively, how much heat energy would need to be supplied to raise the temperature of the glass and water to 90 °C?
    41200 J
30. Explain why steam gives a more severe burn than boiling water.

Steam at 100°C contains more energy than water at 100 °C. This is because steam contains the latent heat of vaporization while water does not. When contacted by hot water or steam, it will cool, releasing its energy to you which causes the burn. The steam has more energy to release so it will cause more severe burns.

Nuclear

1. As part of her medical degree at university, Cynthia is studying Nuclear Medicine. The two atoms she is studying both have mass number 60, but atom ONE has atomic number 28 while atom TWO has atomic number 27. Use this information to fill in the table below:

atom	Nuclide of atom	Number of neutrons	Number of protons
ONE	Ni-60	32	28
TWO	Co-60	33	27

2. Identify "**X**" in each of the following equations and place its symbol in the brackets to the right of the equation. Name what is produce and if a type of radiation, name the radiation not the particle.

a. ${}^{14}_{7}N + {}^{1}_{0}n \rightarrow {}^{14}_{6}C + \mathrm{X}$ [${}^{1}_{1}p$] _proton_

b. ${}^{238}_{92}U \rightarrow {}^{234}_{90}Th + \mathrm{X}$ [${}^{4}_{2}\alpha$] _alpha radiation___

c. ${}^{131m}_{53}I \rightarrow {}^{131}_{53}I + \mathrm{X}$ [${}^{0}_{0}\gamma$] __gamma ray___

(note: m denotes in excited state)

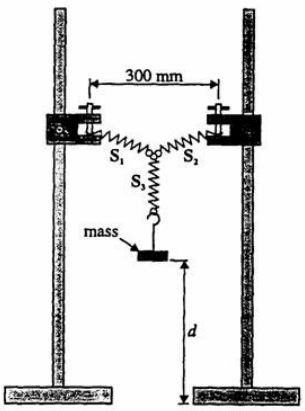
Working Scientifically

1. Lezanne put a hot piece of toast on a cool, dry plate and then lifted it off. She saw drops of water on the plate in the area that had been covered by the toast. Jan thought that the water came from moisture, evaporated from the toast, which had condensed on the plate.

   Which one of the following would help Lezanne by supporting or rejecting her hypothesis? Only one answer is correct.

   a. Measuring the temperature of the plate before and after the toast was on it.
   b. Weighing the toast before and after it was on the plate.
   c. Measuring the temperature of the toast before and after it was on the plate.
   d. Weighing the plate before and after the toast was on it.

2. You can calculate the spring constant for a spring in a school laboratory by placing a mass on a spring in a similar set-up to that shown.

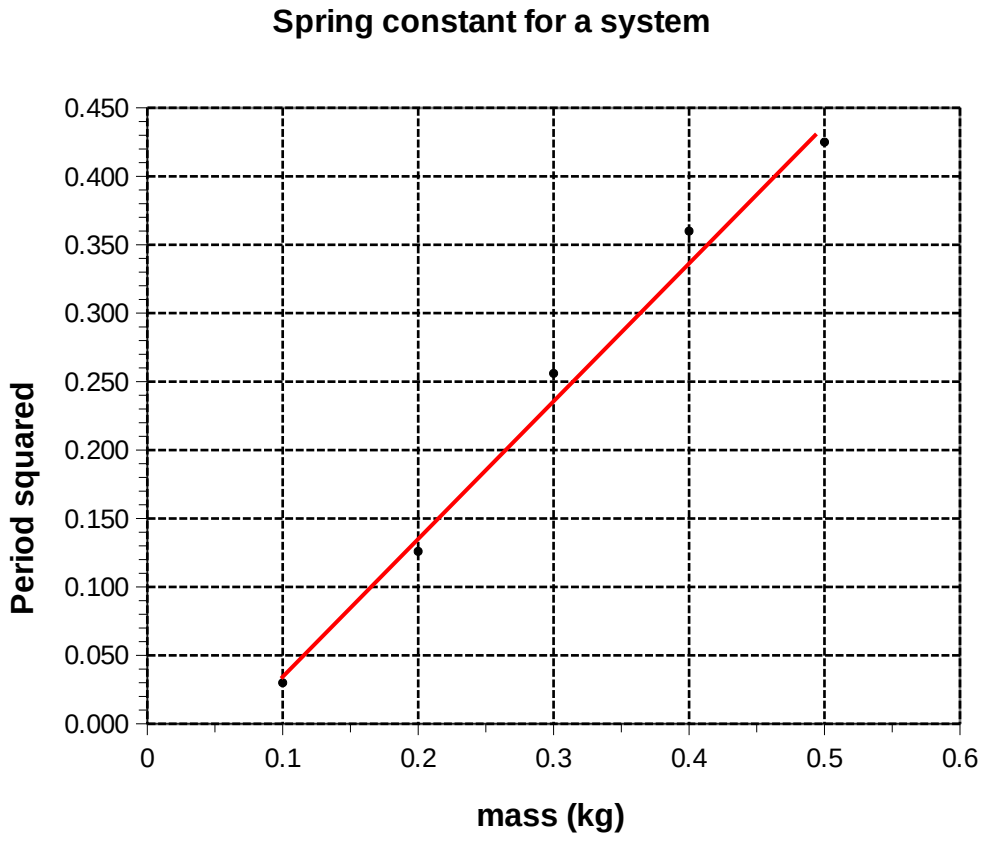


The mass can then be oscillated and the time for 10 oscillations taken. After repeating the trial, more mass is added and then the experiment is repeated. The spring constant, ***k***, can then be calculated using the relationship:

$$T^2 = \frac{4\pi^2 m}{k}$$

A group of students completed the experiment using the equipment set up similar to that shown. They took the appropriate measurements, recorded them and produced the graph below:

a. Complete the graph by drawing a line of best fit.
b. What would be the period for a mass of 0.25 kg? 0.436 s
c. Determine the gradient and value of k. gradient= 1 s^2 kg^{-1} k= 39.5 kg s^{-2}



3. In a Physics investigation, a group of students measures the time (t) for a trolley to roll down a 5.0 m incline starting the trolley from rest. The slope is determined by raising one end of the plank by distance H. After repeating the measurement four times, the students then increases the slope of the incline, and repeats the timing procedure for the trolley to cover the same distance. The students repeat the exercise for four other slopes, the results of which are recorded in the table below.

Height	**Time for the trolley to roll down the slope t (s)**				
H (cm)	t_1	t_2	t_3	t_4	Average
20	5.2	5.1	4.9	5.0	5.05
30	4.2	4.0	4.1	4.1	4.1
40	3.6	3.5	4.2	3.5	3.53
50	3.2	3.1	3.2	3.1	3.15
60	2.9	2.85	2.9	2.1	2.88

a. State the independent and dependent variables for this experiment.

Independent: height of slope

Dependent: time for trolley to roll down the slope

b. List two control variable to make it a valid test.

Constant surface of slope, constant type of ball

c. Explain why the students repeated the trials four times before changing the height.

Repeat trials increase reliability by helping to eliminate some random errors

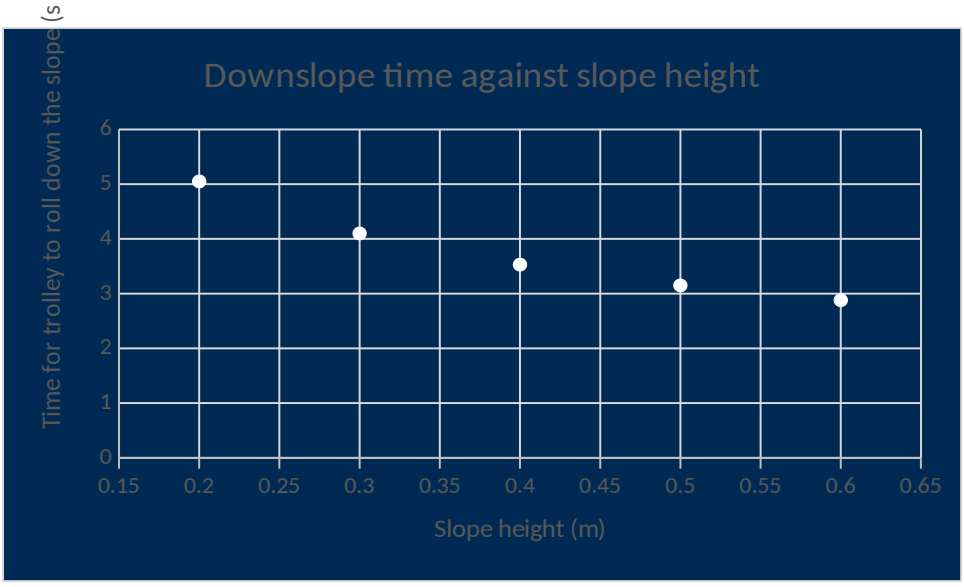
d. Circle any data results you would disregard when finding the average of the results.

e. Explain why you would disregard these results and if it is acceptable to do so.

The two points are notably different from the other points at their heights. All other points at their heights are in close agreement, these are clear outliers so can be ignored.

f. Complete the table by calculating averages.

g. Plot a graph of H against t.



h. Write a conclusion for this investigation based on the data collected and the graph.

As slope height increases the time taken for the trolley to roll down the slope decreases. It does not seem to be a simple linear relationship.
