

Worksheet 6.5: Solutions

The contact process

No.	Answer
1	It was named for its corrosiveness and extremely sour, or 'vitriolic', taste. In these times it was common for the alchemists to taste the chemicals that they had discovered or produced!
2	SO ₂ is produced as a: <ul style="list-style-type: none"> by-product of the desulfurisation of petroleum in the petrochemical industries waste product generated in the smelting of the sulfide ores of non-ferrous metals such as copper, zinc and lead. For example: $2\text{PbS(s)} + 3\text{O}_2\text{(g)} \rightarrow 2\text{PbO(s)} + 2\text{SO}_2\text{(g)}$
3	$2\text{SO}_2\text{(g)} + \text{O}_2\text{(g)} \rightleftharpoons 2\text{SO}_3\text{(g)}; \Delta H = -197 \text{ kJ}$
4	It is necessary to prevent 'poisoning' of the catalyst. (This term indicates that the catalyst is rendered ineffective by dust or contaminants coating its surface.)
5	According to Le Châtelier's principle an increased yield can be achieved by: <ul style="list-style-type: none"> increasing the gas pressure (3 moles of reactant gases produce only 2 moles of product gases, so an increase in pressure would enhance the forward reaction) decreasing the temperature, as the forward reaction is exothermic.
6	Low temperatures ensure a significant yield of sulfur trioxide is formed, but slowly. At high temperatures, the equilibrium yield is poor, but it forms quickly. A compromise in temperature must be reached to achieve acceptable yields quickly. A temperature of about 440°C for the incoming gases is appropriate, and atmospheric pressure is used to save money on the costs associated with high pressure equipment.
7	<p>a Vanadium(V) oxide or vanadium pentoxide</p> <p>b By using trays of pellets, the surface area of the catalyst is increased, and so is its effectiveness.</p> <p>Length of time for contact is carefully controlled because the temperature increases due to the exothermic reaction. At higher temperatures the SO₃ would quickly decompose to SO₂ and O₂.</p>
8	$\text{SO}_3\text{(g)} + \text{H}_2\text{O(l)} \rightarrow \text{H}_2\text{SO}_4\text{(aq)}$ <p>While this direct hydrolysis of SO₃ would be more straightforward, it is highly exothermic and would result in the production of a 'fog' of sulfuric acid droplets.</p> <p>Oleum (H₂S₂O₇) is produced by reacting preformed sulfuric acid with SO₃. The oleum is then reacted with water:</p> $\text{SO}_3\text{(g)} + \text{H}_2\text{SO}_4\text{(l)} \rightarrow \text{H}_2\text{S}_2\text{O}_7\text{(l)}$ $\text{H}_2\text{S}_2\text{O}_7\text{(l)} + \text{H}_2\text{O(l)} \rightarrow 2\text{H}_2\text{SO}_4\text{(aq)}$

Worksheet 6.5: Solutions

The contact process

No.	Answer
9	Both of these gases readily hydrolyse in rainwater to produce sulfurous and sulfuric acids respectively, which are major contributors to acid rain. Relevant equations are: $\text{SO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \rightarrow \text{H}_2\text{SO}_3(\text{aq})$ $\text{SO}_3(\text{g}) + \text{H}_2\text{O}(\text{l}) \rightarrow \text{H}_2\text{SO}_4(\text{aq})$
10	See Figure 6.30 on page 191 of the textbook.
