(a) Prove that "If  $(x - a)$  is a factor of a polynomial, then  $P(a) = 0$ ."

Assume  $P(x)$  is a polynomial of degree  $n$ .

Then  $P(x) = x^n + ax^{n-1} + bx^{n-1} + \dots + k$ .

$$\begin{aligned} P(x) &= x^n + ax^{n-1} + bx^{n-1} + \dots + k \\ &= (x - a)(x^{n-1} + px^{n-1} + \dots + l) \end{aligned}$$

since  $(x - a)$  is a factor.

$$\therefore P(a) = (a - a)(a^{n-1} + pa^{n-1} + \dots + l)$$

$$\therefore P(a) = 0$$

Therefore, if  $(x - a)$  is a factor, then  $P(a) = 0$

The sampling distribution will have a much smaller standard deviation than the original population as each of the points is an estimate of the mean of the population.

The standard deviation of the sampling distributions is found by  $\sigma_{\bar{x}} = \frac{\sigma}{\sqrt{n}}$ .

$$P_1 \quad \sigma_{\bar{x}} = \frac{12}{\sqrt{18}} = 2.83$$

$$P_2 \quad \sigma_{\bar{x}} = \frac{6}{\sqrt{18}} = 1.41$$

$$P_3 \quad \sigma_{\bar{x}} = \frac{18}{\sqrt{18}} = 4.24 \quad \checkmark \checkmark$$

It can be seen that the bigger the population standard deviation, the bigger the standard deviation of the sampling distributions.

- (ii) Each of the sampling distributions are a tightly clustered normal distribution.

$$(a) \quad \frac{dN}{dt} = kN \left( \frac{K - N}{K} \right) \text{ for } r = 0.1 \text{ and } K = 100$$

$$\frac{dN}{dt} = 0.1N \left( 1 - \frac{N}{100} \right) = \frac{0.1N}{100} (100 - N)$$

$$\text{so } \frac{dt}{dN} = \frac{100}{0.1} \left( \frac{1}{N(100 - N)} \right)$$

$$0.001t = \int \left( \frac{1}{N(100 - N)} \right) dN$$

Using partial fractions,

$$\begin{aligned} \frac{1}{N(100 - N)} &= \frac{a}{N} + \frac{b}{100 - N} \\ &= \frac{a(100 - N) + bN}{N(100 - N)} \end{aligned}$$

$$\frac{0 \times N + 1}{N(100 - N)} = \frac{N(b - a) + 100a}{N(100 - N)}$$

$$0 = b - a \text{ and } 1 = 100a$$

$$a = b \text{ and } a = 0.01 = b$$

$$\frac{1}{N(100 - N)} = \frac{1}{100N} + \frac{1}{100(100 - N)}$$

$$\text{so } 0.001t = \int \left( \frac{1}{N(100 - N)} \right) dN \text{ becomes}$$

$$\frac{0.1t}{100} = \int \frac{1}{100N} + \frac{1}{100(100 - N)} dN$$

$$\frac{0.1}{100}t = \frac{1}{100} \left[ \int \frac{1}{N} dN + \int \frac{1}{(100 - N)} dN \right]$$

$$0.1t = \ln N + (-1) \ln(100 - N) + C$$

$$0.1t - C = \ln \left( \frac{N}{100 - N} \right)$$

$$\frac{N}{100 - N} = e^{0.1t - C}$$

$$\frac{100 - N}{N} = Ae^{-0.1t} \text{ where } A = e^C$$

At  $t = 0, N = N_0$

$$\frac{100 - N_0}{N_0} = Ae^0 = A \text{ so } A = \frac{100 - N_0}{N_0}$$

$$\frac{100 - N}{N} = Ae^{-0.1t}$$

Rearrange the formula to get  $N$

$$100 - N = NAe^{-0.1t}$$

$$100 = N(1 + Ae^{-0.1t})$$

$$\therefore N = \frac{100}{1 + Ae^{-0.1t}} \text{ with } A = \frac{100 - N_0}{N_0}$$

(5)

(b) (i)  $K = 610 \Rightarrow N = \frac{610}{1 + Ae^{-kt}} \text{ with } A = \frac{610 - N_0}{N_0}$

At  $t = 0, N_0 = 300$  (Jan 2015)

$$A = \frac{610 - 300}{300} = 1.03$$

$$N = \frac{610}{1 + 1.03e^{-kt}} \quad k = ?$$

At  $t = 12, N_{12} = 400$  (Jan 2016)

$$400 = \frac{610}{1 + 1.03e^{-k \times 12}}$$

$$1 + 1.03e^{-k \times 12} = \frac{610}{400} \Rightarrow k = 0.05642890327$$

$$\therefore N = \frac{610}{1 + 1.03e^{-0.05642890324t}}$$

At  $t = 24, N_{24} = ?$  (Jan 2017)

$$N = \frac{610}{1 + 1.03e^{-0.05642890324 \times 24}}$$

$$N = 481.55$$

The number of trout in the dam in January 2017 is expected to be close to 482.

(5)

(ii)  $N = 600$ ,  $t = ?$ 

$$600 = \frac{610}{1 + 1.03e^{-0.05642890324 \times t}}$$

$$1 + 1.03e^{-0.05642890324 \times t} = \frac{610}{600}$$

$$t = 73.14$$

i.e. expect 600 trout in the dam in February 2021.
