> A census for a particular country showed that 34.8% of people used public transport at some point during a regular week. At about the same time as the census, a sample of people in a region of the country showed that 1573 of those people used public transport at some point during a regular week.

Given $\hat{p} = 0.286$, determine n, the number of people sampled. [1]

$$n = 5500$$

A 90% confidence interval for \hat{p} was calculated and determined to be $0.276 \le \hat{p} \le 0.296$. Comment on the statistical significance of the sample point estimate.

3. (4 marks)

> 28% of orange trees never bear fruit. A wholesaler purchases 126 trees. Use sample proportion techniques to determine the probability that at least one third of these trees will not bear fruit. Show any distributions used.

$$P = 0.28$$

$$O = \sqrt{\frac{0.28(1-0.26)}{126}}$$

$$= \frac{1}{25}$$

$$O \times \times \sim \beta(126, 0.28)$$

$$P(\times > 42) = 0.1097$$

$$\hat{p} \approx N(0.28, \frac{1}{25}^2)$$

$$P(\hat{p}, 7\frac{1}{3}) = 0.0912$$

$$Z = 1.96$$

 $SE = 0.1687$
 $\therefore 95\% \text{ C.I.} = (0.1646, 0.502)$

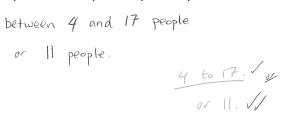

Given that the population proportion (p) is known, comment on the validity of the sample taken. [2]

$$P = \frac{36}{100}$$

= 0.36 is well within the 95% C.I
so the sample is statistically valid.

A second sample of the same population taken by a different methods student indicated the 99% confidence interval to be (0.12, 0.56). [2]

How many workers in the sample do we expect to vote yes?

[3]

have a landline phone. It was found that of the 564 homes surveyed, 223 still had a landline An NBM survey randomly selected Australian homes to ascertain the number of homes that still

Briefly explain a possible random sampling method used to data for the survey.

Determine the standard deviation of the random variable \hat{p} , for samples of 564 homes.

Str9.1 = Z

(c) State a 90% confidence interval for the sample proportion.

sample size of this sample. confidence interval resulted in a margin of error less than 0.05, determine the minimum (d) A further sample of homes resulted in a sample proportion of 0.38. If the 95%

$$\frac{\sqrt{(29.0)88.0}}{96.1} = 20.0$$

5. (9 marks)

There are over 600 000 commercial trucks in Australia. According to recent research, 86% of commercial trucks in Australia satisfy the criteria to be called roadworthy.

(a) Explain why it is likely that the research involved some form of random sampling. [1]

(b) If a large number of random samples of 35 commercial trucks are collected, what proportion of these samples are expected to contain less than 80% of roadworthy trucks?

(c) If a large number of random samples of 200 commercial trucks are collected, what proportion of these samples are expected to contain between 85% and 90% of roadworthy trucks?

adworthy trucks?

$$n = 200$$

 $p = 0.86$
 $O'' = \sqrt{\frac{0.86(0.14)}{200}}$
 $P(0.85 \angle \hat{p}_2 \angle 0.90)$.
 $P(0.85 \angle \hat{p}_2 \angle 0.90)$.
 $P(0.85 \angle \hat{p}_3 \angle 0.90)$.

- (d) One of the answers to (b) or (c) should be treated with some caution. State which answer and explain why. [2]
 - (b) as the sample size is far smaller to that of (c).

6. (5 marks)

A student simulated taking a random sample from a population in which it was known that one out of three people had never been overseas. He then calculated a 90% confidence interval for the population proportion of people who had never been overseas. The confidence interval found was (0.20, 0.46)

He then repeated this process for 9 more random samples. The 90% confidence interval for each proportion was then calculated. The intervals obtained by the student after repeating the simulation nine more times are shown below, rounded to two decimal places.

(a) Determine, with reasoning, whether this group of confidence intervals reflect the population from which the samples are drawn.

Yes, as the pop proportion
$$p = \frac{1}{3}$$
 is within the bounds of 9 of the 10 confidence intervals.

(b) The margin of error for the first interval, (0.20, 0.46) is 0.13.

Calculate the margin of error for the interval (0.11, 0.34), then explain why this is different to the margin of error for the first interval. [3]

$$e = \frac{0.34 - 0.11}{2}$$

A different sample is likely to produce a new β which in turn creates a different value for σ and different c.I.
